Ambient Biomonitoring Network

Delaware River Drainage Basin

1992 Benthic Macroinvertebrate Study

Introduction

Historical Perspective

Since the early 1970's, the Bureau of Water Monitoring (BWM) has been conducting biomonitoring studies on the state's waterbodies. Biomonitoring conducted by the bureau has included both long-term ambient monitoring and intensive surveys.

Between 1977 and 1988 the **Ambient Station Biomonitoring Network** was sampled in cooperation with United States Environmental Protection Agency (USEPA) Region II and Headquarters and the United States Geological Survey (USGS). The resulting biological data was utilized by the 305(b) Program in its evaluations of waterbody impairment. After 1988, funding for ambient biomonitoring was severely curtailed, resulting in the abandonment of routine ambient biomonitoring in the State.

In 1991, BWM received numerous requests from the Office of Regulatory Policy to reactivate the Ambient Biomonitoring Network. The network stations have not been sampled since 1988 and a revisiting of the entire network was overdue. Long-term monitoring data from this network will be most beneficial to the generation of the 305(b) Biennial Report, to the updating of the 303(d) list, to providing the Department with the baseline data necessary to make sound environmental policy decisions in watershed management, and to direct permit activities.

Data Quality Objectives

Accordingly, in 1992 (NJ fiscal year 93), BWM designed and initiated the **Ambient Biomonitoring Network (AMNET)**. The goal of the program is to establish a network of lotic (running water) stations in each major watershed drainage basin. Each watershed drainage basin will be biomonitored for benthic macroinvertebrate populations on a five to six year rotation. The frequency of sampling is reflective of a realistic temporal lag between the cessation of a perturbation and a biological community's recovery from said perturbation. Experience in the 305(b) Program, which reexamines the responses of New Jersey's biological communities to changes in water quality on a two year cycle, has indicated that five years is the optimum frequency for long-term biomonitoring.

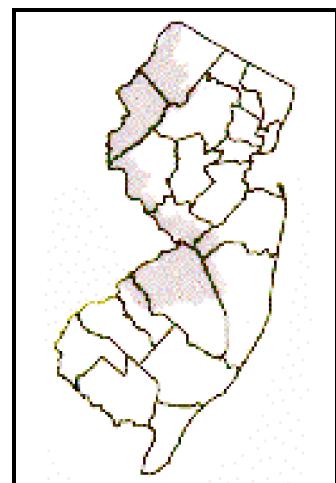

Figure 1 - Study Area

Based upon existing database deficiencies, the area of the Delaware River Drainage Basin shaded in Figure 1 was selected to be monitored during NJ fiscal year 1993 (calendar year 1992). The area was sampled from the sources of its many tributaries down to the Head-of-Tide.

Site Selection

At least one monitoring station has been located on every second order stream and all first order streams at least three miles in length. Stream order is defined as a measure of the position of a stream in the hierarchy of tributaries. First order streams are those with no tributaries, while second order streams are those that have as tributaries only first order streams. The main-stem of the Delaware River was not monitored since the Delaware River Basin Commission (DRBC) already performs biomonitoring along the main-stem of the river.

To the greatest extent possible, the network incorporated existing USGS and New Jersey Department of Environmental Protection (NJDEP) ambient monitoring stations so that correlation of the data sets could be maximized. Furthermore, the network was designed with mainstem (second or third order) stations located before the confluence of major tributaries and with stations located so as to assess the impacts of larger lakes. Known sources of contamination, and significant natural features (i.e., freshwater wetlands, preserves, Fish, Game and Wildlife Management Areas, etc.) were also considered when selecting the sampling locations. **Monitoring station locations in the study area are indicated on the Geographical Information System (G.I.S.) Maps # 12 through 22** (maps 1 - 11 have been deleted). All stations were positioned via the Global Positioning System (GPS), using Trimble Pathfinder Basic Plus global positioning units. Position data was corrected via the NJDEP and University of Rhode Island base station data sets. **Appendix A contains a compilation of all station locations as generated by the GPS.**

Since the objectives of this monitoring network are to provide long-term basin wide biological impact data, the geographical dispersion of the stations was deemed adequate. However, it is likely that the monitoring resolution will not be sufficient to adequately assess the impact of any one point source of pollution. The development of site specific biological impact data is best handled by conducting an intensive biomonitoring survey.

While biological monitoring using benthic macroinvertebrate community structure is an excellent water quality monitoring tool, it is only one branch of water quality monitoring. Additional tools include water column chemistry, sediment chemistry, toxicity testing, fish tissue analysis, and fish community analysis. The most comprehensive evaluation would incorporate all of these elements. However, financial constraints make such monitoring difficult to perform. The frugality of benthic macroinvertebrate analysis provides the water pollution control professional with a holistic assessment of water quality at a reasonable cost.

Methods

Benthic Macroinvertebrate Sampling

The benthic macroinvertebrate sampling was performed in accordance with the procedures delineated in Chapter 7, section K. of the Department's "Field Procedures Manual, NJDEP, May 1992" and, with the following modifications for application to New Jersey's waters, the USEPA's Rapid Bioassessment Protocol II as given in "U.S. Environmental Protection Agency (EPA), 1989, Rapid Bioassessment Protocols For Use In Streams and Rivers, EPA/4444/4-89-001, Assessment and Watershed Protection

Division, Washington D.C." The rapid bioassessment was based upon an evaluation of relatively few samples collected at each station. AMNET's goal is to perform an evaluation of overall biological integrity by capitalizing upon the ability of benthic communities to holistically reflect environmental perturbations. It was imperative, therefore, that sampling be conducted when most of the benthic macroinvertebrates had both attained a size range likely to be retained during standard sieving and sorting, and when in a life stage most conducive to accurate identification. Since most emergence and reproduction occur in the spring and fall, a time when about 80 percent of the macroinvertebrates would be too small to be captured by conventional methods, the period between early June and early September was selected as the optimal collection period. In cases where fall emergence and reproduction were not an issue, sampling could continue into late fall / early winter.

Protocol II of the Rapid Bioassessment (RBPII) employs a systematic field collection of benthic macroinvertebrates and the subsequent analysis of the samples for major taxa. Semiquantitative samples of benthic macroinvertebrates were collected from three different locations at each sampling station. Both riffle/run area samples and Coarse Particulate Organic Matter (CPOM) samples were included in a composite sample for a given station. Using composite samples ameliorates the effects of habitat inconsistency between stations. Samples were collected either with a Surber Sampler, Kick Net, Petite Ponar, or by hand picking. During the field investigation, qualitative observations of habitat, surrounding land use, obvious sources of pollution, and observations of other aquatic biota were made and recorded.

The entire sample collected was sieved through a #30 mesh sieve, put into an appropriate container, preserved with between 5% - 10% formalin (up to 20% formalin was used in cases of excessive organic loading), and transported to the bureau's biomonitoring laboratory for sorting and identification.

Sample Sorting and Identification

The samples were placed on a grid in a small pan with a light colored bottom for the sorting and enumeration of a 100-organism subsample, as per the protocol. The subsampling procedure consisted of evenly distributing the composite sample into the pan. Grids were randomly selected and all organisms within those grids were removed until 100 had been counted. All organisms in the subsample were identified to at least family, though in most cases the identifications were taken to the species level.

Data Analysis

Benthic community biological impairment may be manifested by the absence of pollution sensitive macroinvertebrate taxa (such as Ephemeroptera [mayfly], Plecoptera [stonefly], and Trichoptera [caddisfly]); by excessive dominance by certain taxon (especially pollution tolerant groups such as some Chironomidae [midge] and Oligochaeta [aquatic worm]); by low overall taxa richness; or by perceptible shifts in community structure relative to a reference condition. All of these indicators were utilized in evaluating the RBPII sampling data generated during this study.

The RBPII data analysis protocol is a standardized bioassessment protocol developed by the USEPA in response to a need for a cost effective biomonitoring tool. The RBPII data analysis protocol integrates several community, population, and functional parameters into one easily comprehended evaluation of

biological integrity. This integrated approach to data analysis recognizes that each parameter, or biometric, has different ranges of sensitivity to pollution stresses. An integrated assessment provides increased assurance of validity due to the variety of biometrics evaluated. A deficiency in any one metric for a particular environmental situation is, therefore, less likely to invalidate the study conclusions. The integrated assessment results in each station being given a biological condition category rating, providing the analyst with an easily communicated assessment of relative impairment; this assessment is referred to in this report as the ***Bioassessment Rating***.

The USEPA RBPII data analysis protocol, with some revision, was utilized to evaluate the 1990-92 sample data. Sample station data was evaluated by comparison to a historical database, consisting of 200 benthic macroinvertebrate samples collected in the state, using the impairment criteria developed by Mr. J. Kurtenbach, USEPA - Region II (A Method for Rapid Bioassessment of Streams in New Jersey Using Benthic Macroinvertebrates, Annual Meeting of the North American Benthological Society, Santa Fe, 1991). The bioassessment scores resulting from said analyses are referred to as **NJ Impairment Scores (NJIS)**.

The biometrics used in the assessments are based on family level taxonomy. The NJIS was developed, using the aforementioned database, for evaluating New Jersey biomonitoring stations. Community metric criteria were established for three categories of water quality bioassessment; **non-impaired**, **moderately impaired**, and **severely impaired** (Table 1), using the following metrics: **Taxa Richness**, which reflects the health of a community through a measure of the total taxa; **E+P+T**; the total number of the intolerant forms: *Ephemeroptera*, *Plecoptera*, and *Trichoptera*; **%EPT** (including the hydropsychid family); **%Contribution of the Dominant Family** (%CDF), a measure of community balance based upon the abundance of the numerically dominant taxon relative to the entire population; and **Modified Family Biotic Index** (FBI), which summarizes FTV (Family Tolerance Values) into a single score reflective of organic pollution.

In addition to the metrics listed above, any abnormalities observed in chironomid detritovores, herbivores, and periphyton feeders, demonstrated by number of abnormalities per number of chironomids analyzed for abnormalities, were also used, qualitatively, when developing the final evaluation of biological impairment.

Results and Discussion

The bioassessment ratings developed for each of the monitoring stations were used as the basis for evaluating the degree of biological impairment in the stream segments. In each subbasin, starting from the most downstream station, estimated stream segment bioassessment ratings were assigned by interpolating from the downstream station to the next contiguous upstream station. **The estimated stream segment bioassessment ratings are presented as color coded highlighted segments on each of the G.I.S. Maps # 12 through 22** (maps 1 - 11 have been deleted). These ratings are best estimates of the instream biological impairment based upon the available data. For any given segment the actual instream conditions may be different due to unknown sources of degradation.

Overall, out of 190 monitoring stations sampled during this study period, **46%** were rated as **NON-IMPAIRED**, **37%** were rated as **MODERATELY IMPAIRED**, and **17%** were rated as **SEVERELY IMPAIRED** (see Figure 2).

When the Delaware River Drainage Basin is examined by subbasin groupings, different patterns of biological impairment emerge. The most upstream section of the study area (Clove Brook to Pophandusing Brook) is depicted in Figure 3 (see also maps 12, 13, 14). Only 3% of the drainages are rated as severely impaired, with the majority of the stations (71%) being rated as nonimpaired.

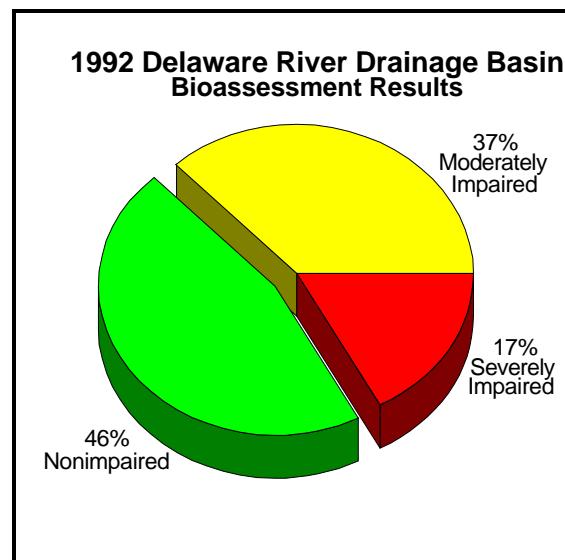

Figure 2

Clove Bk. to Pophandusing Bk. Drainage Bioassessment Results

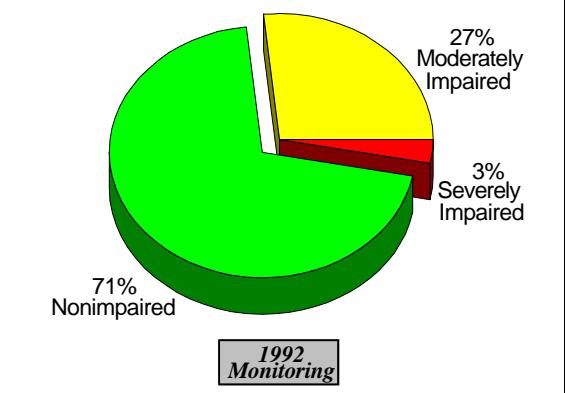

Figure 3

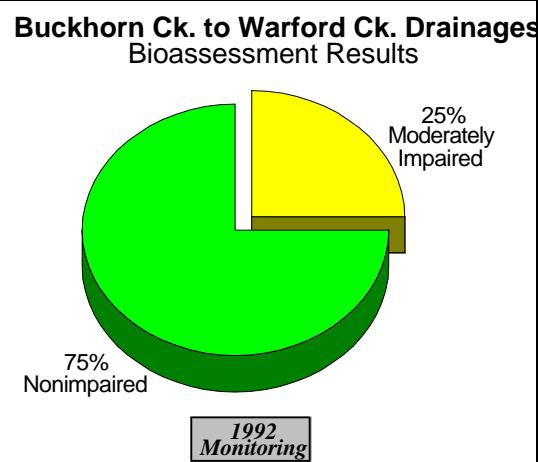

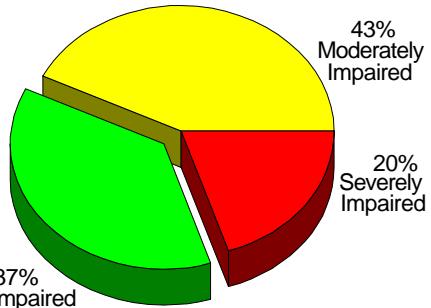

Figure 4

The Buckhorn Creek to Warford Creek drainages depicted in Figure 4 (see also maps 14, 15, 16) show no severely impaired sites and only 25% of the stations being rated as moderately impaired.

The Lockatong Creek to Crosswicks Creek stream drainages in the next downstream group as depicted in Figure 5 (see also maps 16, 17, 18) shows 20% of the sites were severely impaired, and 43% moderately impaired

1992 Monitoring

Figure 6

In the most downstream stations monitored during the study, Swedes Run to Cooper River, as depicted in Figure 7 (see also map 22), the results show that 25% of the stations as being rated moderately impaired, 0% rated as nonimpaired, and 75% being rated as severely impaired.

TABLE 1

**CRITERIA FOR SCREENING
WATER QUALITY IN NEW JERSEY STREAMS**

Scoring Criteria For Rapid Bioassessments¹

Biometrics	6	3	0
Taxa Richness (total Families)	> 10	10-5	4-0
E+ P+ T Index (EPT)	> 5	5-3	2-0
Percent Dominance (%CDF)	< 40	40-60	> 60
Percent EPT ² (%EPT)	> 35	35-10	< 10
Modified Family Biotic Index ³ (FBI)	0-4	4-6	6-10

Biological Assessment	Total Score
Non-impaired	24-30
Moderately Impaired	9-21
Severely Impaired	0-6

Attributes

Non-impaired: Benthic community comparable to other undisturbed streams within the region. A community characterized by a maximum taxa richness, balanced taxa groups and good representation of intolerant individuals.

Moderately Impaired: Macroinvertebrate richness is reduced, in particular EPT taxa. Taxa composition changes result in reduced community balance and intolerant taxa become absent.

Severely Impaired: A dramatic change in the benthic community has occurred. Macroinvertebrates are dominated by a few taxa which are very abundant. Tolerant taxa are the only individuals present.

¹ Based on 100 organism subsamples

² Including the hydropsychid family

³ Also known as the Hilsenhoff Biotic Index

APPENDIX B

Delaware Basin - Port Jervis South USGS Quadrangle

Station AN0001

Clove Brook, Route 23, below Lake Marcia, High Point State Park

January 7, 1993

Family	Number of Individuals	Family Tolerance Value (FTV)
Chironomidae	51	6
Gastropoda	39	7
Hydropsychidae	5	4
Sphaeriidae	1	8
Empididae	1	6
Gammaridae	1	4
Lumbriculidae	1	8
Tubificidae	1	10

Statistical Analysis

Number of Taxa = 8

Total Number of Individuals = 100

% Contribution of Dominant Family = 51

Family Biotic Index = 6.35

Scraper/Filterer Collector Ratio = 0.00

Shredder/Total Ratio = 0.00

E+P+T* = 1 *(Ephemeroptera, Plecoptera and Trichoptera)

%EPT = 5.00

EPT/C* = 0.01 *(Chironomidae)

NJIS Rating = 9

Biological Condition = moderately impaired

Deficiency(s) noted: paucity of clean water organisms

Observations

Streamwater: clear...Flow: slow to mod...Width/Depth(ft): 2/<0.5..

.Substrate: gravel/sand...Streambank Vegetation/Stability: poor/good...Canopy: open...Other: some trees on left bank; parking lot on right bank; channelized with large flat stones

Delaware Basin - Port Jervis South USGS Quadrangle
Station AN0002
Clove Brook, Route 23, Duttonville
January 7, 1993

Family	Number of Individuals	Family Tolerance Value (FTV)
Hydropsychidae	68	4
Limnephilidae	1	4
Corydalidae	1	0
Siphlonuridae	10	7
Chironomidae	13	6
Taeniopterygidae	5	2
Simuliidae	1	6
Philopotamidae	1	3

Statistical Analysis

Number of Taxa = 8
Total Number of Individuals = 100
% Contribution of Dominant Family = 68
Family Biotic Index = 4.43
Scraper/Filterer Collector Ratio = 0.01
Shredder/Total Ratio = 0.05
E+P+T* = 5 *(Ephemeroptera, Plecoptera and Trichoptera)
%EPT = 85.00
EPT/C* = 6.54 *(Chironomidae)
NJIS Rating = 18
Biological Condition = moderately impaired
Deficiency(s) noted: Hydropsychidae overwhelmingly dominant

Observations

Streamwater: clear...Flow: fast...Width/Depth(ft): 20/~1...
Substrate: boulders/cobbles...Streambank Vegetation/Stability:
good/good...Canopy: open...Other: tree-lined; periphyton and
mosses coverage~100%

Delaware Basin - Milford USGS Quadrangle
Station AN0003
Shimers Brook, Millville Road (Route 521), Millville
January 6, 1993

Family	Number of Individuals	Family Tolerance Value (FTV)
